Chapter 5: Process Synchronization

- Background
- The Critical-Section Problem
- Peterson’s Solution
- Synchronization Hardware
- Mutex Locks
- Semaphores
- Classic Problems of Synchronization
- Monitors
- Synchronization Examples
- Alternative Approaches
Objectives

- To present the concept of process synchronization.
- To introduce the critical-section problem, whose solutions can be used to ensure the consistency of shared data.
- To present both software and hardware solutions of the critical-section problem.
- To examine several classical process-synchronization problems.
- To explore several tools that are used to solve process synchronization problems.

Background

- Processes can execute concurrently.
  - May be interrupted at any time, partially completing execution.
- Concurrent access to shared data may result in data inconsistency.
- Maintaining data consistency requires mechanisms to ensure the orderly execution of cooperating processes.
- Illustration of the problem:
  Suppose that we wanted to provide a solution to the consumer-producer problem that fills all the buffers. We can do so by having an integer counter that keeps track of the number of full buffers. Initially, counter is set to 0. It is incremented by the producer after it produces a new buffer and is decremented by the consumer after it consumes a buffer.
Producer

while (true) {
    /* produce an item in next produced */
    while (counter == BUFFER_SIZE) ;
    /* do nothing */
    buffer[in] = next_produced;
    in = (in + 1) % BUFFER_SIZE;
    counter++;
}

Consumer

while (true) {
    while (counter == 0) ; /* do nothing */
    next_consumed = buffer[out];
    out = (out + 1) % BUFFER_SIZE;
    counter--;
    /* consume the item in next consumed */
}
Race Condition

- `counter++` could be implemented as
  
  ```
  register1 = counter 
  register1 = register1 + 1 
  counter = register1 
  ```

- `counter--` could be implemented as
  
  ```
  register2 = counter 
  register2 = register2 - 1 
  counter = register2 
  ```

- Consider this execution interleaving with "count = 5" initially:

  S0: producer execute `register1 = counter`  \(\{\text{register1 = 5}\}\)
  S1: producer execute `register1 = register1 + 1`  \(\{\text{register1 = 6}\}\)
  S2: consumer execute `register2 = counter`  \(\{\text{register2 = 5}\}\)
  S3: consumer execute `register2 = register2 - 1`  \(\{\text{register2 = 4}\}\)
  S4: producer execute `counter = register1`  \(\{\text{counter = 6}\}\)
  S5: consumer execute `counter = register2`  \(\{\text{counter = 4}\}\)

Critical Section Problem

- Consider system of \(n\) processes \(\{p_0, p_1, \ldots, p_{n-1}\}\)
- Each process has critical section segment of code
  - Process may be changing common variables, updating table, writing file, etc
  - When one process in critical section, no other may be in its critical section
- Critical section problem is to design protocol to solve this
- Each process must ask permission to enter critical section in entry section, may follow critical section with exit section, then remainder section
Critical Section

- General structure of process $P_i$

\[
\text{do } \{
\quad \text{entry section}
\quad \text{critical section}
\quad \text{exit section}
\quad \text{remainder section}
\} \text{ while (true)};
\]

Algorithm for Process $P_i$

\[
\text{do } \{
\quad \text{while (turn == j)};
\quad \text{critical section}
\quad \text{turn = j;}
\quad \text{remainder section}
\} \text{ while (true)};
\]
Solution to Critical-Section Problem

1. **Mutual Exclusion** - If process \( P_i \) is executing in its critical section, then no other processes can be executing in their critical sections.

2. **Progress** - If no process is executing in its critical section and there exist some processes that wish to enter their critical section, then the selection of the processes that will enter the critical section next cannot be postponed indefinitely.

3. **Bounded Waiting** - A bound must exist on the number of times that other processes are allowed to enter their critical sections after a process has made a request to enter its critical section and before that request is granted.
   - Assume that each process executes at a nonzero speed.
   - No assumption concerning relative speed of the \( n \) processes.

Critical-Section Handling in OS

Two approaches depending on if kernel is preemptive or non-preemptive:

- **Preemptive** – allows preemption of process when running in kernel mode.
- **Non-preemptive** – runs until exits kernel mode, blocks, or voluntarily yields CPU.
  - Essentially free of race conditions in kernel mode.
Peterson’s Solution

- Good algorithmic description of solving the problem
- Two process solution
- Assume that the load and store machine-language instructions are atomic; that is, cannot be interrupted
- The two processes share two variables:
  - int turn;
  - Boolean flag[2]
- The variable turn indicates whose turn it is to enter the critical section
- The flag array is used to indicate if a process is ready to enter the critical section. flag[i] = true implies that process P_i is ready!

Algorithm for Process P_i

```c
do {
    flag[i] = true;
    turn = j;
    while (flag[j] && turn == j);
        critical section
    flag[i] = false;
        remainder section
} while (true);
```
Peterson’s Solution (Cont.)

- Provable that the three CS requirement are met:
  1. Mutual exclusion is preserved
     - \( P_i \) enters CS only if:
       - either \( \text{flag}[j] = \text{false} \) or \( \text{turn} = i \)
  2. Progress requirement is satisfied
  3. Bounded-waiting requirement is met

Synchronization Hardware

- Many systems provide hardware support for implementing the critical section code.
- All solutions below based on idea of locking
  - Protecting critical regions via locks
- Uniprocessors – could disable interrupts
  - Currently running code would execute without preemption
  - Generally too inefficient on multiprocessor systems
    - Operating systems using this not broadly scalable
- Modern machines provide special atomic hardware instructions
  - Atomic = non-interruptible
    - Either test memory word and set value
    - Or swap contents of two memory words
Solution to Critical-section Problem Using Locks

```c
do {
    acquire lock
    critical section
    release lock
    remainder section
} while (TRUE);
```

test_and_set Instruction

Definition:

```c
boolean test_and_set (boolean *target) {
    boolean rv = *target;
    *target = TRUE;
    return rv;
}
```

1. Executed atomically
2. Returns the original value of passed parameter
3. Set the new value of passed parameter to "TRUE".
Solution using test_and_set()

- Shared Boolean variable lock, initialized to FALSE
- Solution:
  
  ```
  do {
      while (test_and_set(&lock))
       ; /* do nothing */
       /* critical section */
      lock = false;
       /* remainder section */
  } while (true);
  ```

compare_and_swap Instruction

Definition:

```c
int compare_and_swap(int *value, int expected, int new_value) {
    int temp = *value;

    if (*value == expected)
        *value = new_value;
    return temp;
}
```

1. Executed atomically
2. Returns the original value of passed parameter “value”
3. Set the variable “value” the value of the passed parameter “new_value” but only if “value” == “expected”. That is, the swap takes place only under this condition.
Solution using compare_and_swap

- Shared integer “lock” initialized to 0;
- Solution:

  ```c
  do {
    while (compare_and_swap(&lock, 0, 1) != 0) /* do nothing */
    /* critical section */
    lock = 0;
    /* remainder section */
  } while (true);
  ```

Bounded-waiting Mutual Exclusion with test_and_set

```c
do {
  waiting[i] = true;
  key = true;
  while (waiting[i] && key)
    key = test_and_set(&lock);
  waiting[i] = false;
  /* critical section */
  j = (i + 1) % n;
  while ((j != i) && !waiting[j])
    j = (j + 1) % n;
  if (j == i)
    lock = false;
  else
    waiting[j] = false;
  /* remainder section */
} while (true);
```
Mutex Locks

- Previous solutions are complicated and generally inaccessible to application programmers
- OS designers build software tools to solve critical section problem
- Simplest is mutex lock
- Protect a critical section by first acquire() a lock then release() the lock
  - Boolean variable indicating if lock is available or not
- Calls to acquire() and release() must be atomic
  - Usually implemented via hardware atomic instructions
- But this solution requires busy waiting
  - This lock therefore called a spinlock

acquire() and release()

```c
acquire() {
    while (!available)
        ; /* busy wait */
    available = false;
}

release() {
    available = true;
}

do {
    acquire lock
    critical section
    release lock
    remainder section
} while (true);
```
Semaphore

- Synchronization tool that provides more sophisticated ways (than Mutex locks) for process to synchronize their activities.
- Semaphore $S$ – integer variable
- Can only be accessed via two indivisible (atomic) operations
  - `wait()` and `signal()`
    - Originally called $P()$ and $V()$
- Definition of the `wait()` operation
  ```
  wait(S) {
      while ($S \leq 0$) 
          ; // busy wait 
      S--; 
  }
  ```
- Definition of the `signal()` operation
  ```
  signal(S) {
      S++; 
  }
  ```

Semaphore Usage

- **Counting semaphore** – integer value can range over an unrestricted domain
- **Binary semaphore** – integer value can range only between 0 and 1
  - Same as a mutex lock
- Can solve various synchronization problems
- Consider $P_1$ and $P_2$ that require $S_1$ to happen before $S_2$
  - Create a semaphore “synch” initialized to 0
  ```
  P1:
      S_1;
      signal(synch);
  ```
  ```
  P2:
      wait(synch);
      S_2;
  ```
- Can implement a counting semaphore $S$ as a binary semaphore
**Semaphore Implementation**

- Must guarantee that no two processes can execute the `wait()` and `signal()` on the same semaphore at the same time.
- Thus, the implementation becomes the critical section problem where the `wait` and `signal` code are placed in the critical section.
  - Could now have busy waiting in critical section implementation.
    - But implementation code is short.
    - Little busy waiting if critical section rarely occupied.
- Note that applications may spend lots of time in critical sections and therefore this is not a good solution.

**Semaphore Implementation with no Busy waiting**

- With each semaphore there is an associated waiting queue.
- Each entry in a waiting queue has two data items:
  - value (of type integer)
  - pointer to next record in the list.
- Two operations:
  - `block` – place the process invoking the operation on the appropriate waiting queue.
  - `wakeup` – remove one of processes in the waiting queue and place it in the ready queue.
- `typedef struct{
    int value;
    struct process *list;
} semaphore;`
Implementation with no Busy waiting (Cont.)

```c
wait(semaphore *S) {
    S->value--;
    if (S->value < 0) {
        add this process to S->list;
        block();
    }
}

signal(semaphore *S) {
    S->value++;
    if (S->value <= 0) {
        remove a process P from S->list;
        wakeup(P);
    }
}
```

Deadlock and Starvation

- **Deadlock** – two or more processes are waiting indefinitely for an event that can be caused by only one of the waiting processes
- Let $S$ and $Q$ be two semaphores initialized to 1

\[
\begin{align*}
    P_0 & : & P_1 \\
    \text{wait}(S); & & \text{wait}(Q); \\
    \text{wait}(Q); & & \text{wait}(S); \\
    \ldots & & \ldots \\
    \text{signal}(S); & & \text{signal}(Q); \\
    \text{signal}(Q); & & \text{signal}(S);
\end{align*}
\]

- **Starvation** – indefinite blocking
  - A process may never be removed from the semaphore queue in which it is suspended
- **Priority Inversion** – Scheduling problem when lower-priority process holds a lock needed by higher-priority process
  - Solved via priority-inheritance protocol
Classical Problems of Synchronization

- Classical problems used to test newly-proposed synchronization schemes
  - Bounded-Buffer Problem
  - Readers and Writers Problem
  - Dining-Philosophers Problem

Bounded-Buffer Problem

- $n$ buffers, each can hold one item
- Semaphore `mutex` initialized to the value 1
- Semaphore `full` initialized to the value 0
- Semaphore `empty` initialized to the value $n$
Bounded Buffer Problem (Cont.)

- The structure of the producer process

```plaintext
do {
  /* produce an item in next_produced */
  ...
  wait(empty);
  wait(mutex);
  /* add next produced to the buffer */
  ...
  signal(mutex);
  signal(full);
} while (true);
```

Bounded Buffer Problem (Cont.)

- The structure of the consumer process

```plaintext
Do {
  wait(full);
  wait(mutex);
  /* remove an item from buffer to next_consumed */
  ...
  signal(mutex);
  signal(empty);
  /* consume the item in next consumed */
  ...
} while (true);
```
Readers-Writers Problem

- A data set is shared among a number of concurrent processes
  - Readers – only read the data set; they do not perform any updates
  - Writers – can both read and write
- Problem – allow multiple readers to read at the same time
  - Only one single writer can access the shared data at the same time
- Several variations of how readers and writers are considered – all involve some form of priorities
- Shared Data
  - Data set
  - Semaphore rw_mutex initialized to 1
  - Semaphore mutex initialized to 1
  - Integer read_count initialized to 0

Readers-Writers Problem (Cont.)

- The structure of a writer process

```c
    do {
    wait(rw_mutex);
    ...
    /* writing is performed */
    ...
    signal(rw_mutex);
} while (true);
```
Readers-Writers Problem (Cont.)

- The structure of a reader process
  
do {
    wait(mutex);
    read_count++;
    if (read_count == 1)
      wait(rw_mutex);
    signal(mutex);
    ...  
    /* reading is performed */
    ...
    wait(mutex);
    read_count--;
    if (read_count == 0)
      signal(rw_mutex);
      signal(mutex);
  } while (true);

Readers-Writers Problem Variations

- **First** variation – no reader kept waiting unless writer has permission to use shared object
- **Second** variation – once writer is ready, it performs the write ASAP
- Both may have starvation leading to even more variations
- Problem is solved on some systems by kernel providing reader-writer locks
Dining-Philosophers Problem

- Philosophers spend their lives alternating thinking and eating
- Don’t interact with their neighbors, occasionally try to pick up 2 chopsticks (one at a time) to eat from bowl
  - Need both to eat, then release both when done
- In the case of 5 philosophers
  - Shared data
    - Bowl of rice (data set)
    - Semaphore chopstick[5] initialized to 1

Dining-Philosophers Problem Algorithm

- The structure of Philosopher i:
  
  ```
  do {
    wait (chopstick[i] );
    wait (chopStick[ (i + 1) % 5] );

    // eat
    signal (chopstick[i] );
    signal (chopstick[ (i + 1) % 5] );

    // think
  } while (TRUE);
  ```
- What is the problem with this algorithm?
Dining-Philosophers Problem Algorithm (Cont.)

- Deadlock handling
  - Allow at most 4 philosophers to be sitting simultaneously at the table.
  - Allow a philosopher to pick up the forks only if both are available (picking must be done in a critical section).
  - Use an asymmetric solution -- an odd-numbered philosopher picks up first the left chopstick and then the right chopstick. Even-numbered philosopher picks up first the right chopstick and then the left chopstick.

Problems with Semaphores

- Incorrect use of semaphore operations:
  - signal (mutex) …. wait (mutex)
  - wait (mutex) … wait (mutex)
  - Omitting of wait (mutex) or signal (mutex) (or both)

- Deadlock and starvation are possible.
Monitors

- A high-level abstraction that provides a convenient and effective mechanism for process synchronization
- Abstract data type, internal variables only accessible by code within the procedure
- Only one process may be active within the monitor at a time
- But not powerful enough to model some synchronization schemes

```plaintext
monitor monitor-name
{
    // shared variable declarations
    procedure P1 (…) { … }

    procedure Pn (…) {…..}

    Initialization code (…) { … }
}
```

---

Schematic view of a Monitor

- Entry queue
- Shared data
- Operations
- Initialization code

---
Condition Variables

- condition \( x, y \);
- Two operations are allowed on a condition variable:
  - \( x\.\text{wait}() \) – a process that invokes the operation is suspended until \( x\.\text{signal}() \)
  - \( x\.\text{signal}() \) – resumes one of processes (if any) that invoked \( x\.\text{wait}() \)
    - If no \( x\.\text{wait}() \) on the variable, then it has no effect on the variable

Monitor with Condition Variables
Condition Variables Choices

- If process P invokes x.signal(), and process Q is suspended in x.wait(), what should happen next?
  - Both Q and P cannot execute in parallel. If Q is resumed, then P must wait
- Options include
  - **Signal and wait** – P waits until Q either leaves the monitor or it waits for another condition
  - **Signal and continue** – Q waits until P either leaves the monitor or it waits for another condition
  - Both have pros and cons – language implementer can decide
  - Monitors implemented in Concurrent Pascal compromise
    - P executing signal immediately leaves the monitor, Q is resumed
  - Implemented in other languages including Mesa, C#, Java

Monitor Solution to Dining Philosophers

```c
monitor DiningPhilosophers
{
    enum { THINKING, HUNGRY, EATING) state [5];
    condition self [5];

    void pickup (int i) {
        state[i] = HUNGRY;
        test(i);
        if (state[i] != EATING) self[i].wait;
    }

    void putdown (int i) {
        state[i] = THINKING;
        // test left and right neighbors
        test(((i + 4) % 5));
        test(((i + 1) % 5));
    }
}
```
Solution to Dining Philosophers (Cont.)

```c
void test (int i) {
    if ((state[(i + 4) % 5] != EATING) &&
        (state[i] == HUNGRY) &&
        (state[(i + 1) % 5] != EATING) ) {
        state[i] = EATING ;
        self[i].signal () ;
    }
}

initialization_code() {
    for (int i = 0; i < 5; i++)
        state[i] = THINKING;
}
```

Solution to Dining Philosophers (Cont.)

- Each philosopher \(i\) invokes the operations `pickup()` and `putdown()` in the following sequence:

```c
DiningPhilosophers.pickup(i);

EAT

DiningPhilosophers.putdown(i);
```

- No deadlock, but starvation is possible
Monitor Implementation Using Semaphores

- Variables

```plaintext
semaphore mutex; // (initially = 1)
semaphore next;   // (initially = 0)
int next_count = 0;
```

- Each procedure $F$ will be replaced by

```plaintext
wait(mutex);
...
body of F;
...
if (next_count > 0)
  signal(next)
else
  signal(mutex);
```

- Mutual exclusion within a monitor is ensured

Monitor Implementation – Condition Variables

- For each condition variable $x$, we have:

```plaintext
semaphore x_sem; // (initially = 0)
int x_count = 0;
```

- The operation $x.wait$ can be implemented as:

```plaintext
x_count++;
if (next_count > 0)
  signal(next);
else
  signal(mutex);
wait(x_sem);
x_count--;
```
Monitor Implementation (Cont.)

- The operation `x.signal` can be implemented as:

```c
if (x_count > 0) {
    next_count++;
    signal(x_sem);
    wait(next);
    next_count--;
}
```

Resuming Processes within a Monitor

- If several processes queued on condition `x`, and `x.signal()` executed, which should be resumed?
- FCFS frequently not adequate
- **Conditional-wait** construct of the form `x.wait(c)`
  - Where `c` is **priority number**
  - Process with lowest number (highest priority) is scheduled next
Single Resource allocation

- Allocate a single resource among competing processes using priority numbers that specify the maximum time a process plans to use the resource

```java
R.acquire(t);
...
access the resource;
...
R.release;
```

- Where R is an instance of type `ResourceAllocator`

A Monitor to Allocate Single Resource

```java
monitor ResourceAllocator
{
    boolean busy;
    condition x;
    void acquire(int time) {
        if (busy)
            x.wait(time);
        busy = TRUE;
    }
    void release() {
        busy = FALSE;
        x.signal();
    }
    initialization code() {
        busy = FALSE;
    }
}
```
Synchronization Examples

- Solaris
- Windows
- Linux
- Pthreads

Solaris Synchronization

- Implements a variety of locks to support multitasking, multithreading (including real-time threads), and multiprocessing
- Uses adaptive mutexes for efficiency when protecting data from short code segments
  - Starts as a standard semaphore spin-lock
  - If lock held, and by a thread running on another CPU, spins
  - If lock held by non-run-state thread, block and sleep waiting for signal of lock being released
- Uses condition variables
- Uses readers-writers locks when longer sections of code need access to data
- Uses turnstiles to order the list of threads waiting to acquire either an adaptive mutex or reader-writer lock
  - Turnstiles are per-lock-holding-thread, not per-object
- Priority-inheritance per-turnstile gives the running thread the highest of the priorities of the threads in its turnstile
Windows Synchronization

- Uses interrupt masks to protect access to global resources on uniprocessor systems
- Uses spinlocks on multiprocessor systems
  - Spinlocking-thread will never be preempted
- Also provides dispatcher objects user-land which may act mutexes, semaphores, events, and timers
  - Events
    - An event acts much like a condition variable
  - Timers notify one or more thread when time expired
  - Dispatcher objects either signaled-state (object available) or non-signaled state (thread will block)

Linux Synchronization

- Linux:
  - Prior to kernel Version 2.6, disables interrupts to implement short critical sections
  - Version 2.6 and later, fully preemptive
- Linux provides:
  - Semaphores
  - atomic integers
  - spinlocks
  - reader-writer versions of both
- On single-cpu system, spinlocks replaced by enabling and disabling kernel preemption
**Pthreads Synchronization**

- Pthreads API is OS-independent
- It provides:
  - mutex locks
  - condition variable
- Non-portable extensions include:
  - read-write locks
  - spinlocks

**Alternative Approaches**

- Transactional Memory
- OpenMP
- Functional Programming Languages
Transactional Memory

- A memory transaction is a sequence of read-write operations to memory that are performed atomically.

```c
void update()
{
    /* read/write memory */
}
```

OpenMP

- OpenMP is a set of compiler directives and API that support parallel programming.

```c
void update(int value)
{
    #pragma omp critical
    {
        count += value
    }
}
```

The code contained within the `#pragma omp critical` directive is treated as a critical section and performed atomically.
Functional Programming Languages

- Functional programming languages offer a different paradigm than procedural languages in that they do not maintain state.
- Variables are treated as immutable and cannot change state once they have been assigned a value.
- There is increasing interest in functional languages such as Erlang and Scala for their approach in handling data races.

Code Example – file copy (cont’d)

(user) file descriptor table

system file table

active mode tbl

disk

buffer cache

Threads
fileio1.c vs fileio2.c

//main

{……………………

PID = fork(); // child is created before opening/creating files
if((fdrd = open(argv[1], O_RDONLY)) == -1) exit (1);
if((fdwt = creat(argv[2], 0666)) == -1 && ((fdwt = open(argv[2], O_WRONLY)) == -1))
    exit(1);

//PID = fork() is here for fileio2.c
rdwrt();
exit(0);
}

rdwrt()

{for(;;)
{
    if(read(fdrd, &c, 1) != 1) {
        return;
    }
    write(fdwt, &c, 1);
} // of for

// of rdwrt

System V Semaphore

P(wait) V (signal) operations

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>

static void semcall (sid, op)

struct sembuf sb;
sb.sem_num = 0;
sb.sem_op = op;
sb.sem_flg = 0;
if (semop(sid, &sb, 1) == -1)
{
    printf("semop failed.\n");
    exit(0);
}

void P(sid)

int sid;
{
    semcall(sid, -1);
}

void V(sid)

int sid;
{
    semcall(sid, 1);
}
fileioS.c

In main function
....
sid = semget(IPC_PRIVATE, 1, IPC_CREAT|0666);
V(sid);

.............
rdwrt()
{
  for(;;)
  {
    P(sid);
    if(read(frdt, &c, 1) != 1) {
      V(sid);
      return;
    }
    write(fdwt, &c, 1);
    V(sid);
  } // of for
} // of rdwrt

Bounded Buffer Problem Implementation

- Examples using pthread mutex and POSIX Semaphores (see Project: Producer-Consumer Problem at the end of Chapter 6)

- The main():

```c
typedef int buffer_item;
#define BUFFER_SIZE 5

int main() {

  /* Initialize buffer */
  buffer_item buffer[BUFFER_SIZE];

  /* Create producer thread(s) */
  /* Create consumer thread(s) */
  /* Sleep */
  /* Exit */
}
```
End of Chapter 5
